Section outline

Why nonparametrics?

- sometimes just interested in the distribution
- sometimes this is the first stage and we want to integrate
- sometimes want to do something semiparametric

In this section, we are interested in estimating the **density** f(x) under minimal assumptions.

Richard L. Sweeney

Density Estimation

Validation

Example: Auctions

Nonparametric Regression Multivariate Kernels Local linear

Semiparametric

References

Let's start with the histogram

One of the more successful and popular uses of nonparametric methods is estimating the density or distribution function f(x) or F(x).

$$\hat{f}_{HIST}(x_0) = \frac{1}{N} \sum_{i=1}^{N} \frac{\mathbf{1}(x_0 - h < x_i < x_0 + h)}{2h}$$

 Divide the dataset into bins, count up fraction of observations in each bins Example:

Nonparametric Regression Multivariate Kernels

Semiparametric

References

Let's rewrite the histogram estimator

$$\hat{f}_{HIST}(x_0) = \frac{1}{Nh} \sum_{i=1}^{N} K\left(\frac{x_i - x_0}{h}\right)$$

Where
$$K(z) = \frac{1}{2} \cdot \mathbf{1}(|z| < 1)$$

Density estimator interpretation

- for each observation, there is probability mass 1 to spread around
- use the function $K(\cdot)$ and smoothing parameter h to choose how to allocate this mass
- then, for any given x_0 , sum over these functions that spread out mass, and normalize by dividing by N

References

We call $K(\cdot)$ a Kernel function and h the bandwidth. We usually assume

- (i) K(z) is symmetric about 0 and continuous.
- (ii) $\int K(z)dz = 1$, $\int zK(z)dz = 0$, $\int |K(z)|dz < \infty$.
- (iii) Either (a) K(z)=0 if $|z|\geq z_0$ for some z_0 or (b) $|z|K(z)\to 0$ as $|z|\to \infty$.
- (iv) $\int z^K(z)dz = \kappa$ where κ is a constant.

Usually we choose a smooth, symmetric K. But a common nonsmooth choice: K(x)=(|x|<1/2) gives the histogram estimate.

Some Common Kernels

Table 9.1. Kernel Functions: Commonly Used Examples^a

Kernel	Kernel Function K(z)	δ
Uniform (or box or rectangular)	$\frac{1}{2} \times 1(z < 1)$	1.3510
Triangular (or triangle)	$(1- z) \times 1(z < 1)$	_
Epanechnikov (or quadratic)	$\frac{3}{4}(1-z^2) \times 1(z < 1)$	1.7188
Quartic (or biweight)	$\frac{15}{16}(1-z^2)^2 \times 1(z <1)$	2.0362
Triweight	$\frac{35}{32}(1-z^2)^3 \times 1(z <1)$	2.3122
Tricubic	$\frac{70}{81}(1- z ^3)^3 \times 1(z <1)$	_
Gaussian (or normal)	$(2\pi)^{-1/2} \exp(-z^2/2)$	0.7764
Fourth-order Gaussian	$\frac{1}{2}(3-z)^2(2\pi)^{-1/2}\exp(-z^2/2)$	_
Fourth-order quartic	$\frac{15}{32}(3 - 10z^2 + 7z^4) \times 1(z < 1)$	_

^a The constant δ is defined in (9.11) and is used to obtain Silverman's plug-in estimate given in (9.13).

Mean and Variance of $\hat{f}(x_0)$

Assume that the derivative of f(x) exists and is bounded, and $\int zK(z)dz=0$

Then the estimator has bias

$$b(x_0) = E\left[\hat{f}(x_0)\right] - f(x_0) = \frac{1}{2}h^2f''(x_0)\int z^2K(z)dx$$

The variance of the estimator is

$$V\left[\hat{f}(x_0)\right] = \frac{1}{Nh}f(x_0)\int K(z)^2 dz \left\{+o(\frac{1}{Nh})\right\}$$

So, unsurprisingly, the bias is *increasing* in h, and the variance is *decreasing* in h.

Richard L. Sweeney

Density Estimation

Validation

Example: Auctions

Nonparametric Regression Multivariate Kernels Local linear

Semiparametric:

References

How to Choose h

- We want both bias and variance to be as small as possible, as usual.
- In parametric estimation, it is not a problem: they both go to zero as sample size increases.
- In nonparametric estimation reducing h reduces bias, but increases variance; how are we to make his trade off?
- Note that how we set h is going to be much more important than the choice of $K(\cdot)$

References

Mean Integrated Square Error

ullet Start with the *local* performance at x_0

$$MSE\left[\hat{f}(x_0)\right] = E\left[\left(\hat{f}(x_0) - f(x_0)\right)^2\right]$$

Calculate the *integrated* (as opposed to expected) squared error

$$\int \left(\hat{f}(x) - f(x) \right)^2 dx = - \int \mathsf{bias}^2 \left(\hat{f}(x) \right) + \mathsf{var} \left(\hat{f}(x) \right) dx$$

• Simple approximate expression (symmetric order 2 kernels):

$$(\mathsf{bias})^2 + \mathsf{variance} = Ah^4 + B/nh$$

with
$$A = \int (f''(x))^2 (\int u^2 K)^2 / 4$$
 and $B = f(x) \int K^2$

Cross-Validation

Example: Auctions

Nonparametric Regression Multivariate Kernels Local linear

Semiparametrics

References

Optimal bandwidth

• The AMISE is

$$Ah^4 + B/nh$$

• Minimize by taking the FOC

$$h_n^* = \left(\frac{B}{4An}\right)^{1/5}$$

- bias and standard error are both in $n^{-2/5}$
- and the AMISE is $n^{-4/5}$ —not 1/n as it is in parametric models.
- But: A and B both depend on K (known) and f(y) (unknown), and especially "wiggliness" $\int (f'')^2$ (unknown, not easily estimated). Where do we go from here?

Richard L. Sweeney

Density Estimation

Validation

Auctions

parametric Regression Multivariate Kernels Local linear

Semiparametric

References

Optimal bandwidth

Can be shown that the optimal bandwidth is

$$h* = \delta \left(\int f''(x_0)^2 dx_0 \right)^{-0.2} N^{-0.2}$$

where δ depends on the kernel used (Silverman 1986) [these δ 's are given in the kernel table]

Note the "optimal" kernel is Epanechnikov, although the difference is small.

Richard L. Sweeney

Density Estimation

Validation

Nonparametric Regression Multivariate Kernels

Semiparametric

References

Silverman's Rule of Thumb

• If f is normal with variance σ^2 (may not be a very appropriate benchmark!), the optimal bandwidth is

$$h_n^* = 1.06\sigma n^{-1/5}$$

• In practice, typically use Silverman's plug-in estimate:

$$h_n^* = 0.9 * \min(s, IQ/1.34) * n^{-1/5}$$

where IQ=interquartile distance

• Investigate changing it by a reasonable multiple.

This tends to work pretty well. But can we do better?

Cross-validation

• General concept in the whole of nonparametrics: choose h to minimize a criterion CV(h) that approximates

$$AMISE(h) = \int E(\hat{f}_n(x) - f(x))^2 dx.$$

- Usually programmed in metrics software. If you can do it, do it on a subsample, and rescale.
- CV tries to measure what the expected out of sample (OOS or EPE) prediction error of a new never seen before dataset.
- The main consideration is to prevent overfitting.
 - In sample fit is always going to be maximized by the most complicated model.
 - OOS fit might be a different story.
 - ie 1-NN might do really well in-sample, but with a new sample might perform badly.

Richard I Sweenev

Cross-Validation

Multivariate Local linear

Sample Splitting/Holdout Method and CV

Cross Validation is actually a more complicated version of sample splitting that is one of the organizing principles in machine learning literature.

Training Set This is where you estimate parameter values.

Validation Set This is where you choose a model- a bandwidth h or tuning parameter λ by computing the error.

Test Set You are only allowed to look at this after you have chosen a model. Only Test Once: compute the error again on fresh data.

- Conventional approach is to allocate 50-80% to training and 10-20% to Validation and Test.
- Sometimes we don't have enough data to do this reliably.

Challenge with Sample Splitting

FIGURE 5.2. The validation set approach was used on the Auto data set in order to estimate the test error that results from predicting mpg using polynomial functions of horsepower. Left: Validation error estimates for a single split into training and validation data sets. Right: The validation method was repeated ten times, each time using a different random split of the observations into a training set and a validation set. This illustrates the variability in the estimated test MSE that results from this approach.

Reference:

k-fold Cross Validation

- Break the dataset into k equally sized "folds" (at random).
- Withhold i=1 fold
 - Estimate the model parameters $\hat{\theta}^{(-i)}$ on the remaining k-1 folds
 - Predict $\hat{y}^{(-i)}$ using $\hat{\theta}^{(-i)}$ estimates for the ith fold (withheld data).
 - Compute $MSE_i = \frac{1}{k \cdot N} \sum_j (y_j^{(-i)} \hat{y}_j^{(-i)})^2$.
 - Repeat for $i = 1, \ldots, k$.
- Construct $\widehat{MSE}_{k,CV} = \frac{1}{k} \sum_{i} MSE_{i}$

Cross Validation

- Main advantage of cross validation is that we use all of the data in both estimation and in validation.
 - For our purposes validation is mostly about choosing the right bandwidth or tuning parameter.
- We have much lower variance in our estimate of the OOS mean squared error.
 - Hopefully our bandwidth choice doesn't depend on randomness of splitting sample.

Validation
Example:

Nonparametric Regression Multivariate Kernels Local linear

Semiparametrics

References

- In Statistics/Machine learning there is a tradition to withhold 10% of the data as Test Data.
- This is completely new data that was not used in the CV procedure.
- The idea is to report the results using this test data because it most accurately simulates true OOS performance.
- We don't do much of this in economics. (Should we do more?)

Richard L. Sweeney

Density Estimation Cross-

Validation

Example:

Nonparametric Regression Multivariate Kernels Local linear

Semiparametric

Local Bandwidths

If you only care about f(y) at some given point, then

$$A=f''(y)^2\left(\int u^2K\right)^2/4$$
 and $B=f(y)\int K^2.$

So in a low-density region, worry about variance and take h larger. In a curvy region, worry about bias and take h small.

Richard L. Sweeney

Density Estimation

Back to the CDF

Since now we have estimated the density with

$$\hat{f}_n(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - x_i}{h}\right),$$

a natural idea is to integrate; let $\mathcal{K}(x) = \int_{-\infty}^x K(t)dt$, try

$$\hat{F}_n(y) = \frac{1}{n} \sum_{i=1}^n \mathcal{K}\left(\frac{y - y_i}{h}\right)$$

as a reasonable estimator of the cdf in y.

Very reasonable indeed:

- when $n\longrightarrow \infty$ and h goes to zero (at rate $n^{-1/3}\dots$) it is consistent at rate \sqrt{n}
- it is nicely smooth
- by construction it accords well with the density estimator
- ... it is a much better choice than the empirical cdf.

Example application: Auctions

- Why auctions?
- Great introduction to structural approach. Arguably the most successful application.
- Auctions are an example of a game with assymetric information: participants know the primitives of the game, but do not know their rivals exact valuations.
- By imposing rationality/ profit maximization, we can recover the distribution of values.
- Can then run counterfatuals

For more detail, check out Chris Conlon's slides in this folder, or John Asker's PhD lecture notes.

Cross-Validation

Example: Auctions

Nonparametric Regression Multivariate Kernels Local linear

Semiparametrics Let's consider the first price sealed bid (FPSB) auction Denote the equilibrium bid as B_i , with realizations b_i

Perfect Bayes Nash equilibrium:

$$\max_{\tilde{b}} \left(E\left[U_i | X_i = x_i \right] - b, \max_{j \in N_{-i}} B_j \le \tilde{b} \right)$$
$$Pr\left(\max_{j \in N_{-i}} B_j \le \tilde{b} | X_i = x_i \right)$$

Richard L. Sweeney

Estimation

Example:

Nonparametric Regression Multivariate Kernels

Semiparametrics

Reference:

Can find bid as a function of primitives

$$v(x_i, \mathbf{x_i}; N) = b_i + \frac{G_{M_i|B_i}(b_i|b_i; N)}{g_{M_i|B_i}(b_i|b_i; N)}$$

where $G_{M_i \mid B_i}$ and $g_{M_i \mid B_i}$ are the CDF and PDF of the max bids given b_i and N

- we are typically interested in the LHS
- RHS is stuff we can observe or compute
- nice linear structure makes this easy to work with
- Guerre, Perrigne and Vuong (2000): can leverage assumption of equilibrium best response and invertibility of b to recover v

Reference:

Estimation strategy |

[Assumption: FPSB with symmetric IPV]

1 Leverage independence assumption:

$$G_{M_i|B_i}(m_i|b_i; N) = G_{M_I|n}$$

= $Pr(max_{j \neq i}B_j \leq m_i|n)$

2 Value equation becomes

$$u = b + \frac{G_B(b|n)}{(n-1)g_B(b|n)}$$

where G and g are the marginal distribution of bids and the densities in n bidder auctions

 $oldsymbol{3}$ can estimate G and g using kernels

Sweenev

Example:

Auctions

Multivariate Local linear

Richard L.

now have

Estimation strategy | |

$$\hat{u} = b + \frac{\hat{G}_B(b|n)}{(n-1)\hat{g}_B(b|n)}$$

5 finally, can recover the distribution of values with another kernel

$$\hat{f}(u) = \frac{1}{T_n h_f} \sum_{T=1}^{n} \frac{1}{n_t} \sum_{i=1}^{n} K\left(\frac{u_i - \hat{u}_{it}}{h_f}\right)$$

Bias Variance Decomposition

We can decompose any estimator into two components

$$\underbrace{E[(y-\hat{f}(x))^2]}_{MSE} = \underbrace{\left(E[\hat{f}(x)-f(x)]\right)^2}_{Bias^2} + \underbrace{E\left[\left(\hat{f}(x)-E[\hat{f}(x)]\right)^2\right]}_{Variance}$$

- In general we face a tradeoff between bias and variance.
- In k-NN as k gets large we reduce the variance (each point has less influence) but we increase the bias since we start incorporating far away and potentially irrelevant information.
- In OLS we minimize the variance among unbiased estimators assuming that the true f is linear.
- A natural alternative is to use kernels or local smoothers

Richard L. Sweeney

Common weights

Another option is to extend density discussion we just had to two dimensions using local weighted averages

$$\hat{m}(x_0) = \sum_{i=1}^{N} w_{i0,h} y_i$$

Rearranging, can see that OLS uses the following weights

$$\hat{m}_{OLS}(x_0) = \sum_{i=1}^{N} \left\{ \frac{1}{N} \frac{(x_0 - \bar{x})(x_i - \bar{x})}{\sum_{j} (x_j - \bar{x})^2} \right\} y_i$$

CT note that these weights can actually *increase* with the distance between x_0 and $x_i!$ (for example if $x_i > x_0 > \bar{x}$)

Richard L. Sweeney

Density Estimation

Validation Example:

Nonparametric Regression Multivariate Kernels

Semiparametric

References

k-NN is simply a running average

$$\hat{m}_k(x_0) = \frac{1}{k} (y_{i-(k-1)/2} + \dots + y_{i+(k-1)/2})$$

Of course, we could also average all the observations within some bandwidth \boldsymbol{h}

$$\hat{m}(x_0) = \frac{\sum_{i=1}^{Nh} K\left(\frac{x_i - x_0}{h}\right) y_i}{\sum_{i=1}^{Nh} K\left(\frac{x_i - x_0}{h}\right)}$$

where $K(\cdot)$ is a kernel weighting function as above.

Nonparametric Regression

Nadaraya-Watson, inspired from kernel idea:

$$\hat{m}_n(x) = \frac{\sum_{i=1}^n y_i K\left(\frac{x-x_i}{h}\right)}{\sum_{i=1}^n K\left(\frac{x-x_i}{h}\right)}.$$

again, bias in h^2 and variance in 1/nh if $p_x = 1$.

References

Choosing h

- Plug-in estimates work badly.
- Fortunately, cross-validation amounts to

$$\min_{h} \sum_{i=1}^{n} \frac{(g(y_i, x_i) - \hat{m}_n(x_i; h))^2}{1 - k_i(h)}$$

where
$$k_i(h) = K_h(0) / \sum_{j=1}^n K_h(x_i - x_j)$$
.

 So not that hard, and can be done on a subsample and rescaled.

Curse of Dimensionality

Take a unit hypercube in dimension p and we put another hypercube within it that captures a fraction of the observations r within the cube

- Since it corresponds to a fraction of the unit volume, r each edge will be $e_p(r) = r^{1/p}$.
- $e_{10}(0.01) = 0.63$ and $e_{10}(0.1) = 0.80$, so we need almost 80% of the data to cover 10% of the sample!
- If we choose a smaller r (include less in our average) we increase variance quite a bit without really reducing the required interval length substantially.

Curse of Dimensionality

FIGURE 2.6. The curse of dimensionality is well illustrated by a subcubical neighborhood for uniform data in a unit cube. The figure on the right shows the side-length of the subcube needed to capture a fraction r of the volume of the data, for different dimensions p. In ten dimensions we need to cover 80% of the range of each coordinate to capture 10% of the data.

Curse of Dimensionality

Don't worry, it only gets worse:

$$d(p, N) = \left(1 - \left(\frac{1}{2}\right)^{1/N}\right)^{1/p}$$

- d(p,N) is the distance from the origin to the closest point.
- N=500 and p=10 means d=0.52 or that the closest point is closer to the boundary than the origin!
- Why is this a problem?
- In some dimension nearly every point is the closest point to the boundary – when we average over nearest neighbors we are extrapolating not interpolating.

Density/Distribution Estimation

One of the more successful and popular uses of nonparametric methods is estimating the density or distribution function f(x) or F(x).

- Estimating the CDF is easy and something you have already done
- Q-Q plots, etc.

$$\hat{F}_{ECDF}(x_0) = \frac{1}{N} \sum_{i=1}^{N} (x_i \le x_0)$$

• Differentiating to get density is unhelpful : $F_{ECDF}'(x) = 0$ in most places.

What if y is of dimension $p_y > 1$?

"Easy": use p_y -dimensional K (often a p_y -product of 1-dim kernels) and bandwidth h, and do

$$\hat{f}_n(y) = \frac{1}{nh_y^p} \sum_{i=1}^n K\left(\frac{y - y_i}{h}\right).$$

- 1st minor pitfall: the various dimensions may have very different variances, so use (h_1, \ldots, h_{p_n}) .
- 2nd minor pitfall: they may be strongly correlated; then sphericize first.
- Major problem: next slide...

The Curse of Dimensionality

- Computational cost increases exponentially.
- Much worse: to achieve precision ϵ in dimension p_y , the number of observations you need increases as

$$n \simeq \epsilon^{-(2+p_y/2)}.$$

• The *empty space* phenomenon: if (y_1,\ldots,y_{p_y}) all are iid uniform on [-1,1], then only $n/(10^{p_y})$ observations on average have all components in [-0.1,0.1]. Bias still in h^2 , but variance in $1/nh^{p_y}$ now.

Silverman's Table

Silverman (1986 book) provides a table illustrating the difficulty of kernel estimation in high dimensions. To estimate the density at 0 of a N(0,1) with a given accuracy, he reports:

Dimensionality Required	Sample Size
1	4
2	19
5	786
7	10,700
10	842,000

Not to be taken lightly... in any case convergence with the optimal bandwidth is in $n^{-2/(4+p_y)}$ now—and Silverman's rule of thumb for choosing h_n^* must be adapted too.

Usually we care about conditional densities

That is: we have covariates x, we want the density f(y|x). Again, "easy":

- $oldsymbol{0}$ get a kernel estimator of the joint density f(y,x);
- 2 and one of of the marginal density f(x);
- 3 then define

$$\hat{f}_n(y|x) = \frac{\hat{f}_n(y,x)}{\hat{f}_n(x)} = \frac{\frac{1}{nh_y^{p_y}h_x^{p_x}} \sum_{i=1}^n K\left(\frac{y-y_i}{h_y}\right) K\left(\frac{x-x_i}{h_x}\right)}{\frac{1}{h_y^{p_y}} \sum_{i=1}^n K\left(\frac{x-x_i}{h_x}\right)}.$$

But the joint density is $(p_x + p_y)$ dimensional... and the curse strikes big time.

Local Linear Regression I

We can interpret the standard kernel estimator as estimating a constant regressino function $g(\boldsymbol{x}) = m$

where

$$\hat{m} = \arg\min_{m_0} \sum_{i=1}^{N} K\left(\frac{x_i - x_0}{h}\right) \cdot (y_i - m_0)^2$$

Taking the FOC, we see that this yields

$$\hat{g}(x) = \hat{m} = \sum_{i=1}^{N} K\left(\frac{x_i - x_0}{h}\right) \cdot y_i / \sum_{i=1}^{N} K\left(\frac{x_i - x_0}{h}\right)$$

Local Linear Regression II

This suggests other functions instead of constants (that is why we're interested in this regression in the first place!)

A natural option is local linear regression:

$$m(x) = \alpha + \beta(x - x_0)$$

where

$$(\hat{\alpha}, \hat{\beta}) = \arg\min_{m_0} \sum_{i=1}^{N} K\left(\frac{x_i - x_0}{h}\right) \cdot (y_i - \alpha + \beta(x_i - x_0))^2$$

Local Linear Regression III

Advantages:

• the bias becomes 0 if the true m(x) is linear.

• the coefficient of $(x-x_i)$ estimates m'(x).

• behaves better in "almost empty" regions.

Disadvantages: hardly any, just do it!

How to do it: TK lowess in CT page 320

FIGURE 6.3. The locally weighted average has bias problems at or near the boundaries of the domain. The true function is approximately linear here, but most of the observations in the neighborhood have a higher mean than the target point, so despite weighting, their mean will be biased upwards. By fitting a locally weighted linear regression (right panel), this bias is removed to first order.

FIGURE 6.4. The green points show the equivalent kernel $l_i(x_0)$ for local regression. These are the weights in $\hat{f}(x_0) = \sum_{i=1}^{N} l_i(x_0) y_i$, plotted against their corresponding x_i . For display purposes, these have been rescaled, since in fact they sum to 1. Since the yellow shaded region is the (rescaled) equivalent kernel for the Nadaraya-Watson local average, we see how local regression automatically modifies the weighting kernel to correct for biases due to asymmetry in the smoothing window.

Nonparametric Regression, summary, 1

Nadaraya-Watson for E(y|x) = m(x)

$$\hat{m}(x) = \frac{\sum_{i} y_i K_h(x - x_i)}{\sum_{i} K_h(x - x_i)}$$

- bias in $O(h^2)$, variance in $1/(nh^{p_x})$
- optimal h in $n^{-1/(p+4)}$: then bias, standard error and RMSE all converge at rate $n^{-2/(p+4)}$
- to select h, no rule of thumb: cross-validate on a subsample and scale up.

Nonparametric Regression, summary, 2

Nadaraya-Watson=local constant regression: to get $\hat{m}(x)$,

- 1 regress y_i on 1 with weight $K_h(x-x_i)$
- 2 take the estimated coeff as your $\hat{m}(x)$.

Better: local linear regression

- **1** regress y_i on 1 and $(x_i x)$ with weight $K_h(x x_i)$
- 2 take the estimated coeffs as your $\hat{m}(x)$ and $\hat{m}'(x)$.

To estimate the standard errors: bootstrap on an undersmoothed estimate (so that bias is negligible.)

$\begin{array}{c} {\sf Seminonparametric} \; (=& {\sf Flexible}) \\ {\sf Regression} \end{array}$

- This is a parametric approximation that becomes more accurate as the sample size increases (series of sieves)
- Idea: we add regressors when we have more data, eventually providing an arbitrarily close approximation to the true regression function
- Polynomial Example: $m(x; \beta_K) = \sum_{j=1}^K \hat{\beta}_j x^j$
- ullet Given K, just estimate model using OLS
- In practice, you'll want to choose K using leave-one-out cross validation.

Splines: trading off fit and smoothness

- Another option is to use splines
- Idea: Approximate regression function locally using (low order) polynomials, then connect these polynomials at knots.
- The regression function will be continuous at the knots, but not as many times differentiable as elsewhere
- For example, can estimate a linear spline with an intercept and separate slopes depending on whether $x>x_0$

Example: Auctions

Nonparametric Regression Multivariate Kernels Local linear

Semiparametric

Another common option is

$$\min_{m(.)} \sum_{i}^{N} (y_i - m(x_i))^2 + \lambda J \int (m''(x))^2 dx$$

where λ is a ${\bf smoothing}$ ${\bf parameter}$ and m is a cubic polynomial

Then we "obtain" the natural cubic spline with $knots=(x_1,\ldots,x_n)$:

- m is a cubic polynomial between consecutive x_i 's
- it is linear out-of-sample
- it is C^2 everywhere.

"Consecutive" implies one-dimensional...harder to generalize to $p_{x}>1. \label{eq:px}$

Orthogonal polynomials: check out Chebyshev, $1, x, 2x^2 - 1, 4x^3 - 3x \dots$ (on [-1, 1] here.)

References

Review: What was the point?

- OLS is lowest variance among linear unbiased estimators.
- But there are nonlinear estimators and potentially biased estimators.
 - Everything faces a bias-variance tradeoff.
 - Nearly anything can be written as Kernel.
